INTRODUCTION

Auditory feedback important mechanism in speech production [1]

- **Perturbation** of auditory feedback during speech production elicits a **compensatory response** in the opposite direction to maintain the intended auditory outcome [2].
- Plays an **important role in speech motor learning**, i.e. the acquisition of speech motor programs [3].
- Auditory perturbation experiments may help to **understand early development of auditory-motor integration**.

Research question:

- To what extent **are children able to compensate for and adapt to auditory feedback perturbation** throughout their developmental trajectory?

METHODOLOGY

Participants

- 15 children: 8 female, 7 male; age range 4;1 - 8;7 y;m, mean 5;8 y;m.
- 37 adults: 32 female, 5 male; age range 19 - 29 years, mean 22,4 year.

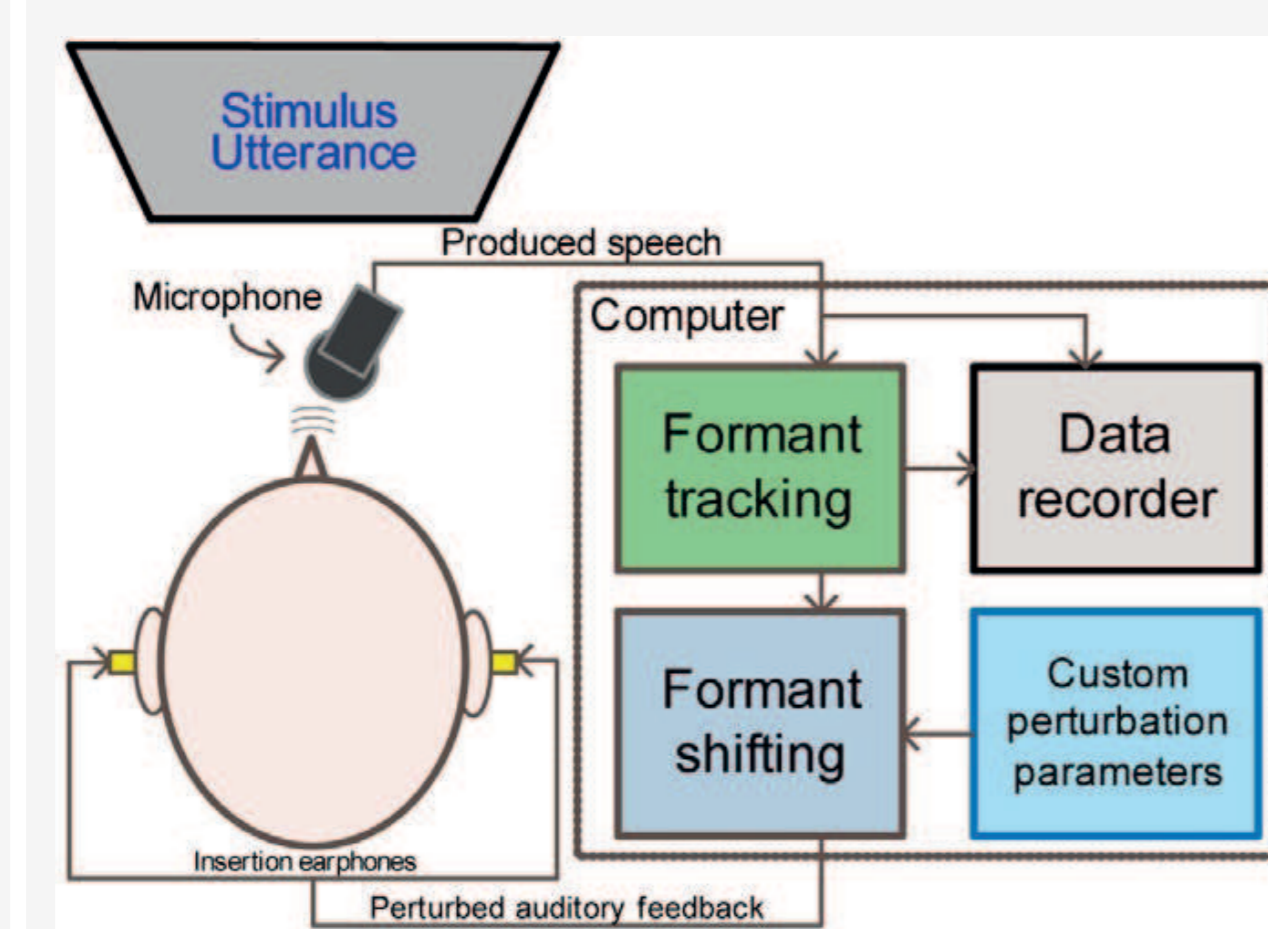

Procedure

- Stimuli: CVC words /be:r/ (bear), /ve:r/ (feather), /pe:r/ (pear).
- Participants were seated in front of a PC-monitor showing pictures of the target words.
- A bird flying over one of the pictures cued the participant to say the intended word.

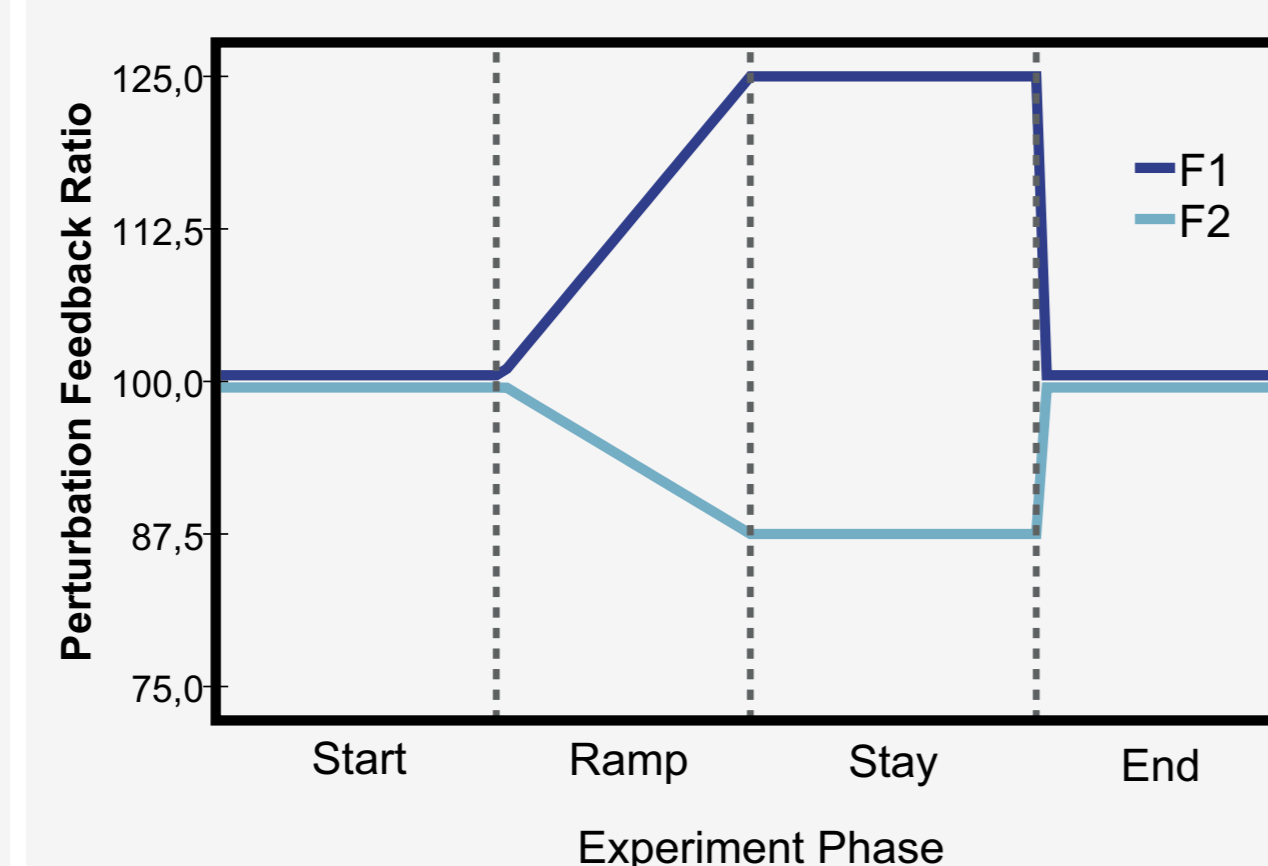

PERTURBATION PARADIGM AND ANALYSIS

- **Experimental setup** Real-time acoustic tracking and shifting of F1 and F2 using Matlab based software package Audapter [5].
- F1 raised 25%; F2 lowered 12.5%.
- Paradigm with 5 phases: Practice - Start - Ramp - Stay - End.
- **Length** adults and children > 7 y/o: 111 words; children ≤ 7 y/o: 84 words.
- **Analysis** F1 and F2 were measured from steady-state portions of the produced vowels using custom PRAAT-scripts.
- **Compensation** differences in formant frequencies between the Start and Stay phase. This is a measure of motor learning: the ability to notice and act on the mismatch between the motor command and the corresponding auditory result.

Experimental setup (from [4])

Perturbation feedback paradigm

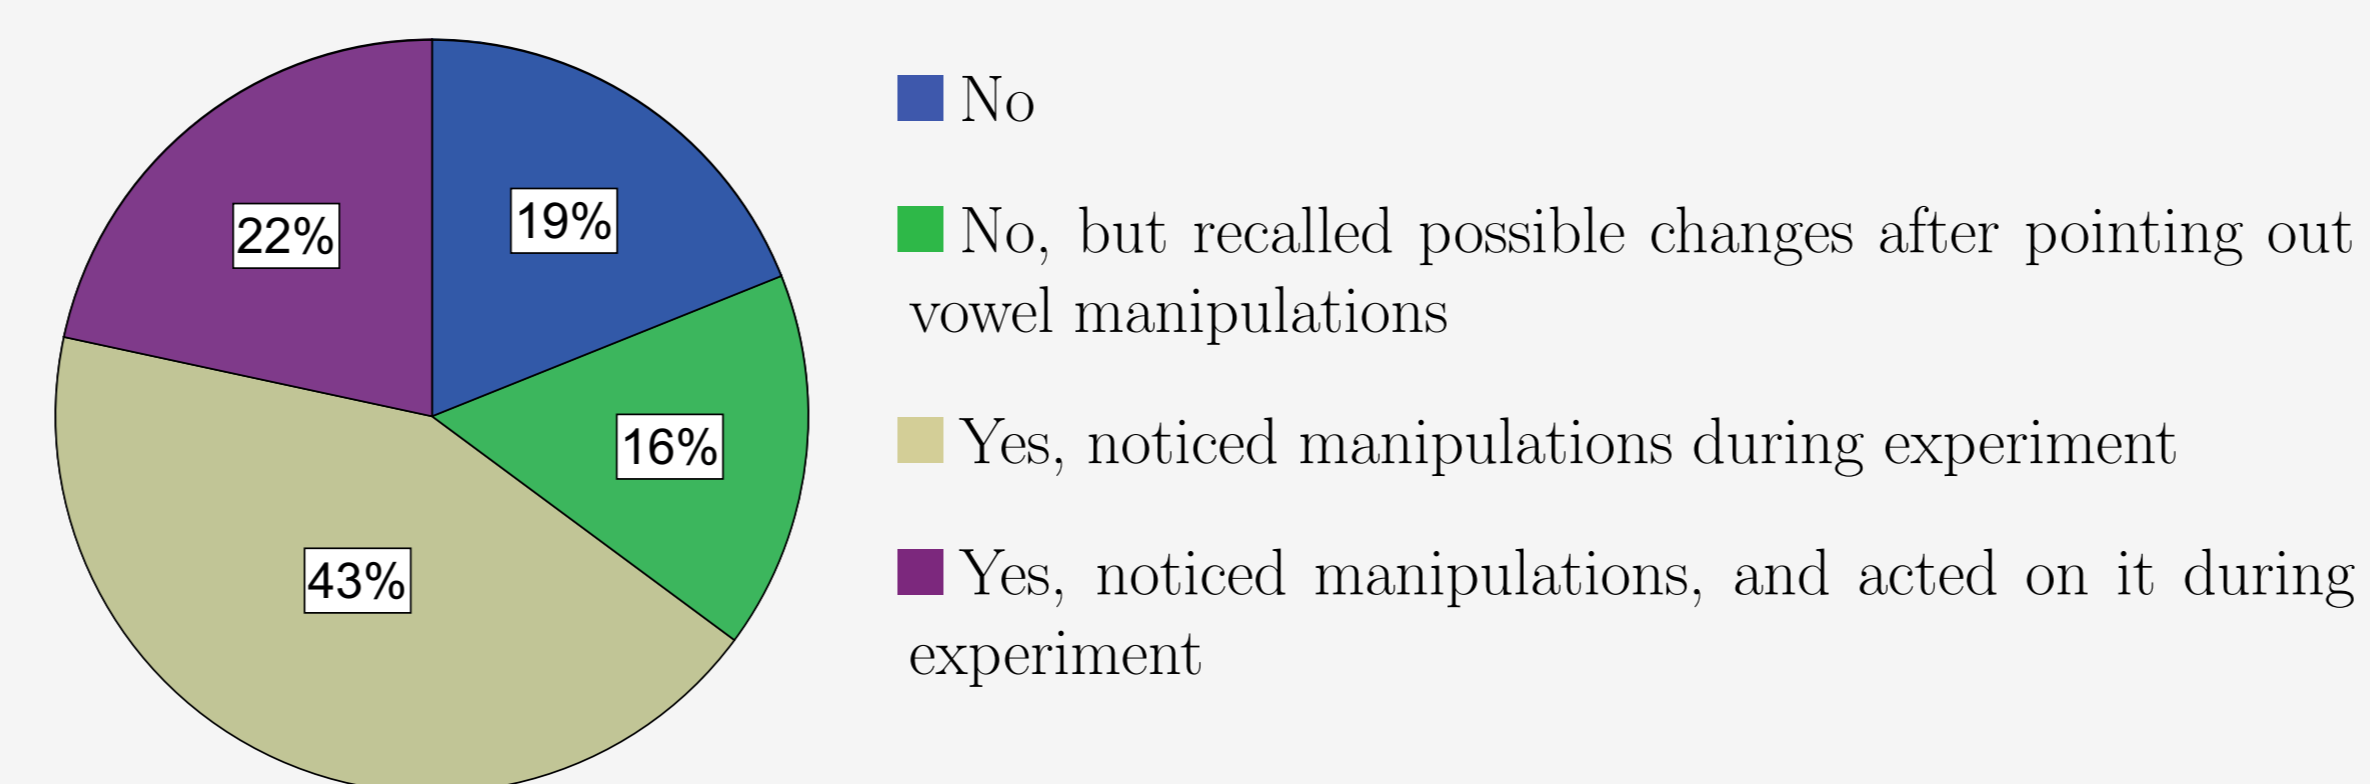

- **Adaptation** differences between the Start and End phase. This is a measure of the after-effect of change in the motor command, followed by recovery (de-adaptation).
- **Statistical analyses** differences across groups and phases using Linear Mixed Model analyses with fixed factors Group and Phase; random factor Subject; repeated factors Phase, Word, Repetition.

RESULTS

EXPERIMENT DEBRIEFING

- Previous studies reported participants were unable to notice perturbations.
- In this study, around 65% indicated to have heard something (and some took action).

“Did you hear something odd when listening to your own voice?”

- **Crosstabs analyses:** no correlation between debriefing and F1/F2 perturbation.

ANALYSIS OF COMPENSATION AND ADAPTATION

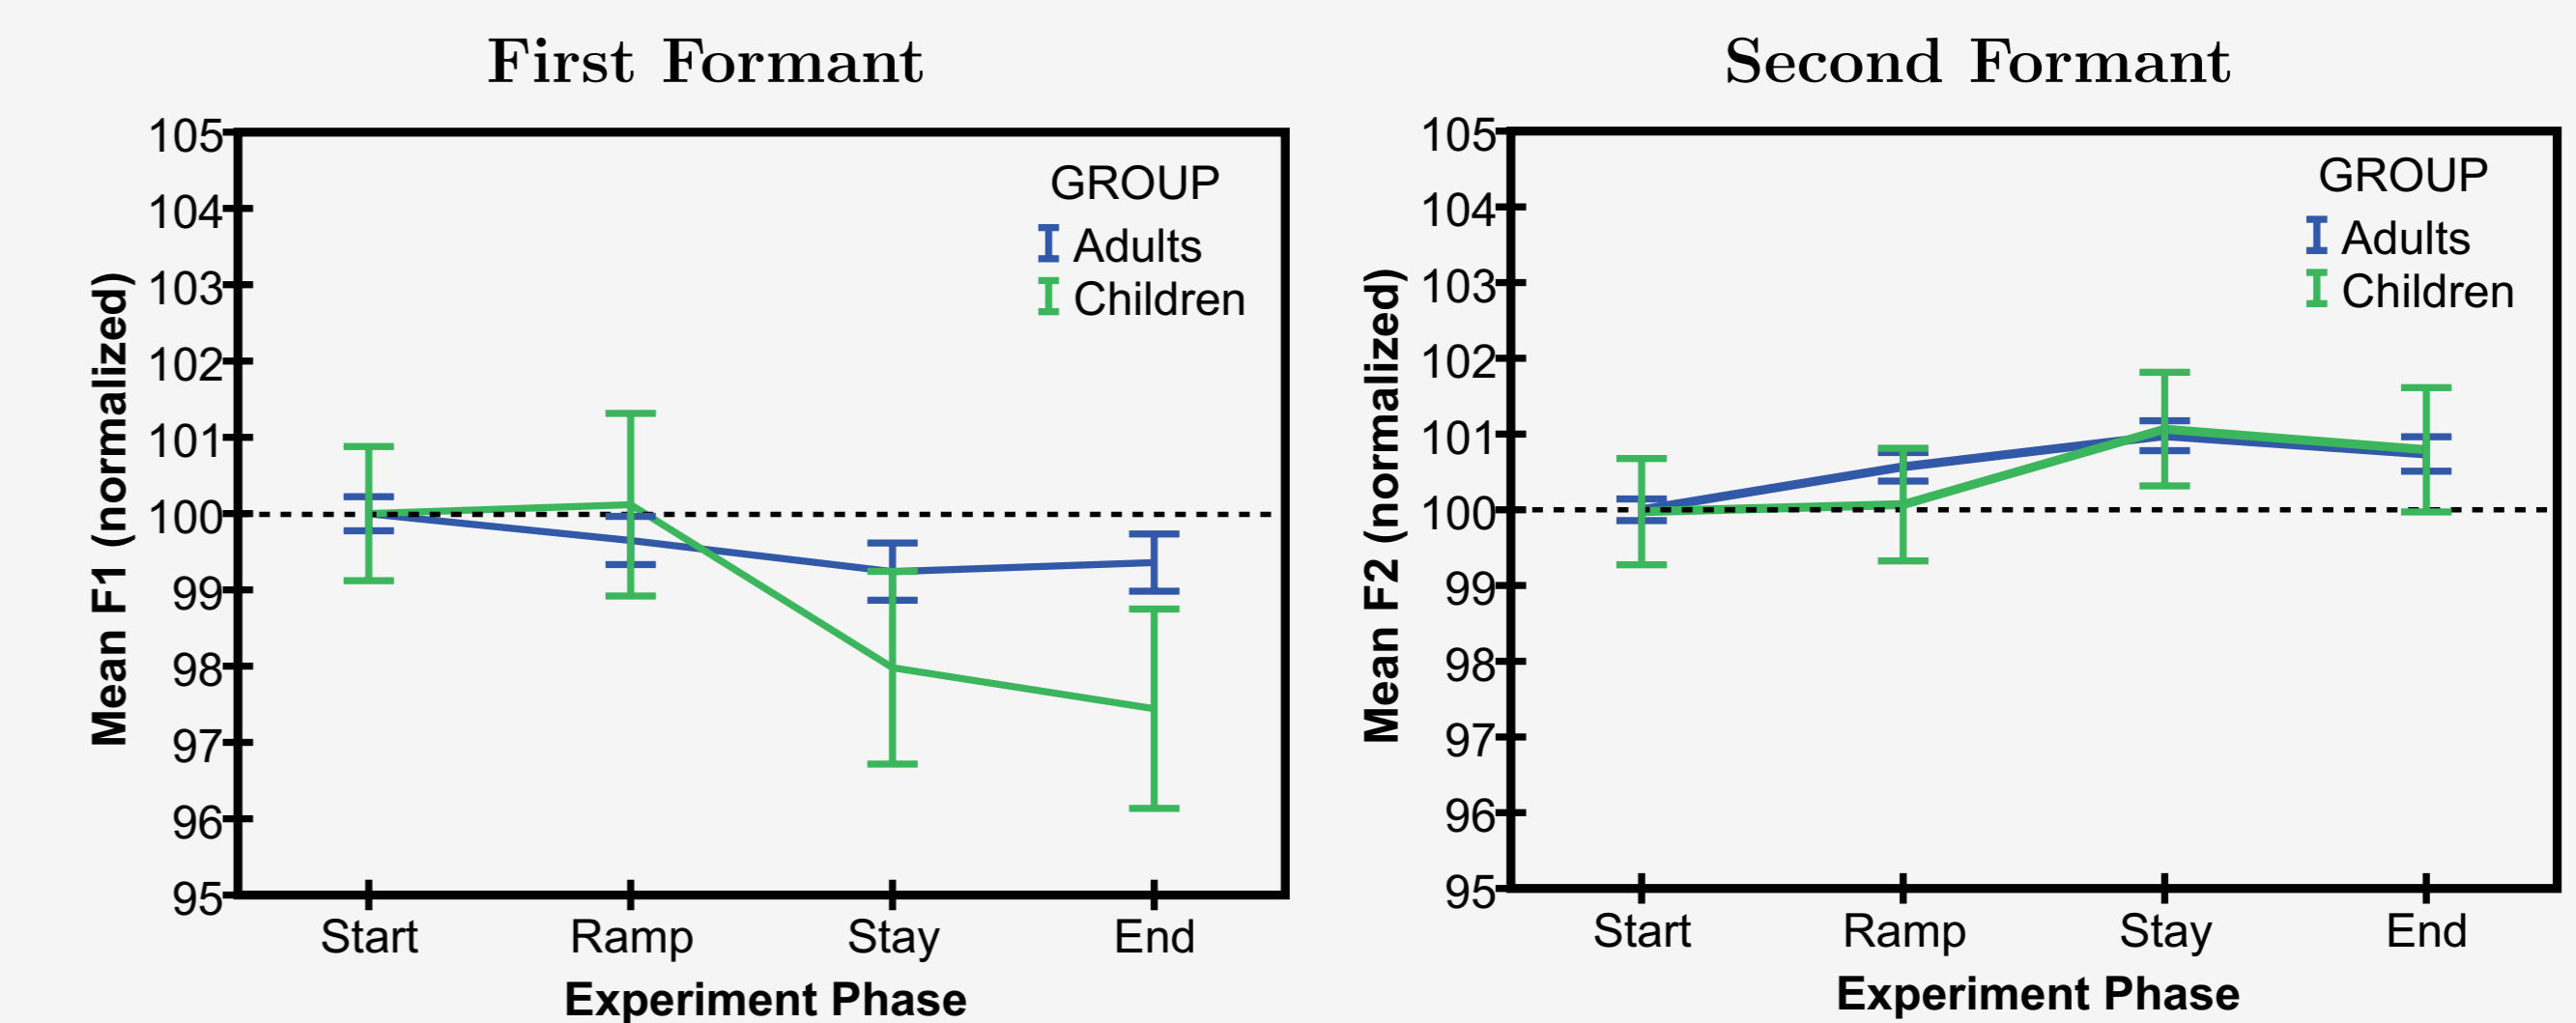

LMM results First Formant

- **Group:** $F(1,2121) = 16.2, p < .001$; **Phase:** $F(2,2140) = 15.2, p < .001$;
- **Group x Phase:** $F(2,2140) = 4.0, p = .018$.
- Post-hoc: Adults showed compensation ($p = .005$), but no adaptation ($p = .093$).
- Children showed compensation and adaptation (both $p < .001$).
- No group differences in Start phase: $p = .591$; children showed stronger compensation in Stay phase: $p = .004$, and stronger adaptation in End phase: $p = .003$.

LMM results Second Formant

- **Group:** $F(1,2132) = 2.0, p = .155$; **Phase:** $F(2,2147) = 18.3, p < .001$;
- **Group x Phase:** $F(2,2147) = .209, p = .811$.
- Post-hoc: Adults showed significant compensation and adaptation (both $p < .001$).
- Children showed significant compensation ($p = .003$), but no adaptation ($p = .063$).
- No group differences in Start: $p = .100$; Stay: $p = .354$; or End: $p = .786$.

RESULTS OF F1 AND F2 PRODUCTIONS

EFFECT OF AGE

Is it possible to detect developmental changes with respect to compensation and/or adaptation?

DISCUSSION

Compensation and adaptation across groups

- **Stronger effect of compensation** for the group of children suggests **auditory-motor properties are less ingrained** compared to adult speakers.
- Presence of adaptation effects of F1 suggest **ramp and stay phase lengths are adequate**, even during the shorter program for children.
- Stronger/longer adaptation in F1 for children suggests that **adults revert faster to the ingrained original representation** of the speech sound.
- Absence of adaptation in F2 for children is possibly due to a **high within-group variance**.

Developmental effects

- Absence of age-related effects for children may be due to several reasons: lack of data; large within-group variability; or... storage and learning strategies of auditory-motor integration do not change significantly in the age span of 4-8 years?
- Within-group differences might be due to different strategies; somatosensory vs auditory focus [6].
